Interoperability Process Reference Manual (IPRM)

THE SGIP

43
44
45 The Smart Grid Interoperability Panel (SGIP) is a membership-based organization established by NIST and
46 administered by a NIST contractor to provide an open process for stakeholders to participate in providing
47 input and cooperating with NIST in the ongoing coordination, acceleration and harmonization of standards
48 development for the Smart Grid. The SGIP also reviews use cases, identifies requirements and architectural
49 reference models, coordinates and accelerates Smart Grid testing and certification, and proposes action
50 plans for achieving these goals. The SGIP does not write standards, but serves as a forum to coordinate the
51 development of standards and specifications by many standards setting organizations.

96 **Preface**

97

98 **About the SGTCC**

99 The Smart Grid Testing & Certification Committee (SGTCC) is a standing committee within the
100 Smart Grid Interoperability Panel (SGIP), the organization initiated by the National Institute of
101 Standards and Technology (NIST) to coordinate standards deployment for the Smart Grid. The
102 SGTCC mission is the creation of

- 103 • organizational frameworks,
- 104 • methodologies and
- 105 • documentation

106 relating to compliance testing and product certification on Smart Grid interoperability and cyberse-
107 curity based standards.

108

109 The SGTCC is composed of a broad range of volunteers with expertise in testing and product certi-
110 fication associated with utilities, vendors, independent test labs, accreditation bodies, associations
111 and consortia that operate certification programs, standards bodies and government. The SGTCC
112 is open to all interested individuals with testing and certification expertise and responsibility, with
113 leadership provided by an SGIP-elected panel of approximately 30 voting participants.

114

115 **Contact the SGTCC**

116 Questions or comments about this document, as well as general inquiries about the SGTCC may
117 be directed to:

118 Rik Drummond, SGTCC Chairman (rikd@drummondgroup.com)

119 or

120 Rudi Schubert, SGTCC Program Administrator (rschubert@energex.com)

Interoperability Process Reference Manual (IPRM)

1. IPRM Executive Summary

The SGTCC has developed and issued this Interoperability Process Reference Manual (IPRM) detailing its recommendations on processes and best practices that enhance the introduction of interoperable products in the market place. These recommendations build upon international standards based processes for interoperability testing and certification.

Implementation of the IPRM by Interoperability Testing and Certification Authorities (ITCAs) will increase the quality of standards-based, secure and interoperable products in the Smart Grid marketplace.

The SGTCC believes that implementation of the IPRM will lead to reduced deployment costs of Smart Grid systems and devices, and enhanced product quality with respect to interoperability and conformance, ultimately providing increased end-user customer satisfaction, and confidence to the buyer through meaningful certification programs.

The IPRM is a key foundational element of the SGIP Testing and Certification Framework. It will enable the adoption of consistent and measurable certification and testing policies and procedures across Smart Grid products (utilizing standards) based on the conformance, interoperability, and cybersecurity testing experience and expertise of SGTCC participants, and the widely accepted ISO/IEC 17025 and ISO/IEC Guide 65 international standards for testing laboratory and certification body management systems.

The ISO/IEC testing and certification standards provide a solid foundation for the development and operation of high quality testing and certification programs. The SGTCC also recognized that additional technical requirements and best practices are necessary to help assure test program tech-

Interoperability Process Reference Manual (IPRM)

147 nical depth and sufficiency in meeting end user expectations for interoperability and cybersecurity.
148 These additional recommendations are detailed in this IPRM.

149 **1.1. Purpose and Problem Statement**

150
151 The IPRM is intended to enhance the validity and consistency of testing and certification programs
152 for standards based products in the market place to help assure their conformance and interopera-
153 bility for the end user/buyer.

154
155 The SGTCC has identified the need for testing and certification programs with uniform quality pro-
156 cesses (ISO 9001, *Quality Management Systems - Requirements* based) across all products
157 based on Smart Grid standards. Additionally there is a need for third party assessment and accred-
158 itation services to be available to help assure that these programs achieve the technical and quality
159 expectations of end users.

160
161 Trusted 3rd party certification programs require specific and detailed test requirements, pass/fail
162 metrics, and defined processes to enable a consistent and well-understood approach to testing
163 and the subsequent assessment of the test certified results. There can be little left to interpretation
164 as a vague or undefined process will lead to inconsistent application and conclusions providing
165 negligible benefit to end users.

166
167 3rd party, independent and trusted certification programs associated with some of the Smart Grid
168 standards under consideration for the SGIP Catalogue of Standards do exist, however there is sig-
169 nificant variability across those programs with respect to the depth of testing and the detailed pro-
170 cesses, policies and practices in place to support the granting of certification. This presents an ad-
171 ditional dimension to the problem as there is a need for all Smart Grid certification programs to be
172 meaningful and rigorous to increase end user confidence in their product decisions related to in-
173 teroperability between products and systems.

Interoperability Process Reference Manual (IPRM)

174

175 The IPRM seeks to address these issues described above and provide the recommendations of
176 the SGTCC in structuring robust testing and certification programs, and the means to assess the
177 success of ITCA's in their implementation of the IPRM recommendations.

178

179 **1.2. Testing Flow Model**

180

181 Currently, standards are developed by industry and vendors use these standards for their product
182 design and testing. Testing may be done internal to the vendor, onsite at a utility or other end user
183 laboratory, or working with an independent provider of testing services.

184

185 This model is straight forward and useful; however in the absence of a broader framework, there
186 are broad variants in the approach and depth of testing programs, leading to uncertainty in whether
187 or not the testing is achieving the needs of end users. A number of current industry programs offer
188 options for certification, usually for conformance to a specification. However a majority of programs
189 simply include basic testing and result reporting, and do not go so far as to certify conformance or
190 especially interoperability. Thus the end buyer is not assured of conformance and interoperability
191 quality products in the market place.

192

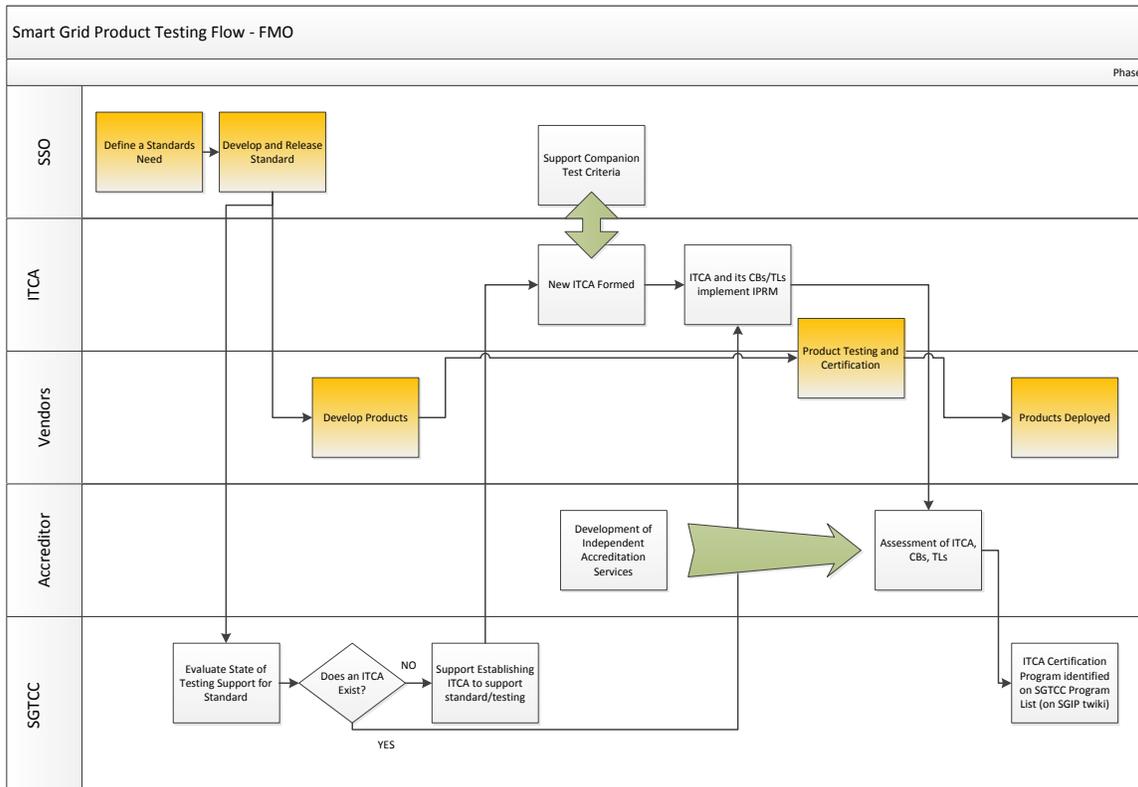

193 The diagram below illustrates one possible future testing model proposed by the SGTCC for Smart
194 Grid systems and devices. It goes beyond the various basic programs currently available introduc-
195 ing a new concept of ITCA's as test and certification program owners responsible for implementing
196 a consistent high quality framework across test programs within their scope of operations. Addi-
197 tionally, accreditation bodies are introduced to independently validate that ITCA certification bodies
198 and test labs are indeed adhering to the recommended practices. This will provide greater confi-
199 dence to end users in products that exhibit interoperability and conformance. It should be noted

Interoperability Process Reference Manual (IPRM)

200 that this specific testing model may not be applicable for all situations; however the core concepts
 201 are recommended by the SGTCC where practical for implementation.

202
 203

204

Figure 1 – Smart Grid Product Testing Flow – Proposed Model

205

1.3. Intended Audience

206

207
 208 The IPRM is the center of the SGIP’s testing and certification framework, and as such affects a
 209 broad range of stakeholders. The IPRM most directly affects and is operationalized by:

- 210 • Interoperability Testing and Certification Authorities (ITCAs),
- 211 • Certification Bodies (ISO/IEC Guide 65),

Interoperability Process Reference Manual (IPRM)

- 212 • Test Laboratories (ISO/IEC 17025) and
213 • Accreditation bodies.

214 System and device vendors are also key stakeholders both in how the IPRM affects their products
215 under test, and their internal test laboratory operations. End users and buyers are the customers
216 and should be able to expect interoperable products in the market place. In addition, the value of
217 IPRM implementation is enhance where these customer understand the standards and associated
218 certifications, and include specific interoperability and certification requirements in RFPs.

219

220 The IPRM defines the responsibilities within and among the ITCA, SSO (Standards Setting Organi-
221 zations), accreditors, test lab(s) and the certification body designed to bring interoperable stand-
222 ards based products to market. The IPRM implementation is facilitated through the use of check
223 lists to ensure key areas are addressed. It is also important that ITCAs communicate well with end
224 users in conveying the value of the certifications that they provide and how they may be used in
225 assessing and achieving product interoperability.

226

227 These responsibilities require detailed processes, which are left to the individual ITCA to define.
228 However, the IPRM **REQUIRES** that product certification be issued by an ISO/IEC 65 accredited
229 third party independent of the testing organization. This follows the logic promulgated in the two
230 basic international management guidelines used as a foundation for the Framework: ISO/IEC
231 17025, *General Requirements for the Competence of Testing and Calibration Laboratories*, and
232 ISO/IEC Guide 65, *General Requirements for Bodies Operating Product Certification Systems*.

233

Interoperability Process Reference Manual (IPRM)

2. International Guidelines for Testing and Certification

The SGTCC extensively investigated and discussed the critical operational processes that independent certification bodies and laboratories need to implement to instill end user confidence in interoperable products. It was quickly concluded that international standards, particularly ISO/IEC Guide 65, General Requirements for Bodies Operating Product Certification Systems¹, and ISO/IEC 17025, General Requirements for the Competence of Testing and Calibration Laboratories², were so broadly used and supported, that adoption of these standards for Smart Grid interoperability was a more prudent approach than developing customized criteria that would simply parallel these accepted standards. Further, there is already a system of accrediting organizations and processes in place that support accreditations of testing and certification functions based on these international standards.

2.1. Overview of ISO/IEC 17025

ISO/IEC 17025 is focused on test laboratories and contains requirements that labs need to demonstrate that they operate a quality management system, are technically competent, and are able to generate technically valid results. It incorporates all requirements of ISO 9001, Quality Management Systems – Requirements, that are relevant to testing services and facilitates acceptance of test results from accredited laboratories. Accreditation bodies apply these requirements in their laboratory assessments.

ISO/IEC 17025 can be applied to any testing lab operation, whether independent (i.e. third-party) laboratories or in-house laboratories operated by manufacturers for their own internal product test-

¹ http://www.iso.org/iso/catalogue_detail.htm?csnumber=26796

² <http://www.iso.org/iso/search.htm?qt=iso+17025&searchSubmit=Search&sort=rel&type=simple&published=on>

Interoperability Process Reference Manual (IPRM)

258 ing. The advantage of applying ISO/IEC 17025 for Smart Grid testing operations is that many labs
259 have already pursued and achieved compliance for selected aspects of the services they offer, and
260 can simply expand their scope of accreditation to encompass new services necessary to support
261 Smart Grid interoperability. This approach will build on common best practices used across the
262 testing industry, speeding implementation and avoiding unnecessary creation of redundant pro-
263 cesses.

264

265 ISO/IEC 17025 focuses on two major areas of laboratory operations:

- 266 1) Management requirements and
- 267 2) Technical requirements.

268

269 The management requirements address issues such as a lab's documented practices (i.e. both
270 administrative and technical), impartiality of the lab in its operations, responsibilities for continuous
271 improvement and issues resolution, and the active support and involvement of lab management in
272 ensuring commitment to complying with these criteria.

273 The technical requirements focus on areas such as ensuring that lab staff are competent in per-
274 forming their testing duties, ensuring that the lab environment is adequate for services performed,
275 ensuring that test plans and other necessary operating instructions are documented and available,
276 and that necessary equipment and software used for testing is calibrated, maintained and appro-
277 priate for its intended usage.

278

279 The criteria described in ISO/IEC 17025 are extensive and the brief description above simply pro-
280 vides a high level view of some of the key elements that labs need to address in attaining accredi-
281 tation.

282

283 The technical scope of accreditation is specific to the selected tests / services for which the lab
284 applies for evaluation. Evaluations for compliance can be performed by a number of different ac-

Interoperability Process Reference Manual (IPRM)

285 crediting bodies, and there are global and regional agreements in place that provide for broad ac-
286 ceptance of an accreditation once attained.

287

288 **2.2. Overview of ISO/IEC Guide 65**

289

290 ISO/IEC Guide 65 is for certification bodies and parallels many of the same concepts applied in
291 ISO/IEC 17025 test laboratories. There are general criteria that assure that the organization is
292 non-exclusionary, open and without conflict of interest. Documented administrative policies and
293 processes, as well as documented technical requirements and specifications for certification, are
294 among the required criteria. Criteria are also included to assure that procedures are in place to
295 describe the granting of certifications, as well as ongoing maintenance, extensions and termina-
296 tions of certifications once granted. Personnel qualifications are addressed for those involved in
297 the evaluation and decision making process associated with the organization's certifications. As in
298 the case for ISO/IEC 17025, this is only a brief description of highlights associated with the more
299 extensive criteria described in the document.

300

301 While these international standard guidelines provide a solid foundation for the development and
302 operation of high quality testing and certification programs, the SGTCC also recognized that addi-
303 tional technical requirements and best practices are necessary to help ensure test program tech-
304 nical depth and sufficiency in meeting end user expectations for interoperability and cybersecurity.
305 These supplemental criteria are described in subsequent sections of this document.

306

307 The IPRM adds an additional REQUIREMENT over and above ISO/IEC Guide 65 -- the independent trust-
308 ed 3rd party certification authority MUST only allow the statement that products are interoperable only if the
309 products actually demonstrated interoperability during testing. They MUST not assume interoperability from
310 conformance testing. They MUST demonstrate it before it may be part of the products certification state-
311 ment.

312

Interoperability Process Reference Manual (IPRM)

313 **3. Overview of IPRM Version 2**

314 This section provides an overview of how this Interoperability Process Reference Manual has
315 changed in this latest version and the organization of the document.

316

317 **3.1. Changes from Version 1**

318 Version 1 of the IPRM was released in January 2011. That version provided extensive background
319 information considered by the SGTCC in the assessment of the state of Smart Grid conformity and
320 interoperability programs, and provided extensive information that would be valuable to readers
321 that may have limited background in testing program models and approaches.

322

323 The general goal of this revision was to enhance the utility of the document to support implementa-
324 tion of the criteria and recommendations by an ITCA and to structure it in a way to better facilitate
325 assessments of ITCA implementation both internal to the ITCA and for external independent as-
326 sessments. The changes in structure and clarity are major. The changes in content are minor.

327

328 Fundamentally, Version 2 has an operational focus, while Version 1 provided an informational fo-
329 cus. Most of the key informative material from Version 1 has been retained in this update. The main
330 body of the IPRM emphasizes the operational aspects, while the informational material is provided
331 in a series of separate informational annexes to the document.

332

333 Significant changes in IPRM Version 2 as compared to the prior version include:

334

- 335 • Removal of informational/background material --- these removed sections have been tran-
336 sitioned to a new background document that the SGTCC is preparing for release during
337 the first half of 2012
- 338 • Greater emphasis on the importance of independent accreditation and adherence to inter-
339 nationally recognized standards for testing labs and certification bodies

Interoperability Process Reference Manual (IPRM)

- 340
- 341
- 342
- 343
- 344
- 345
- 346
- 347
- 348
- 349
- 350
- 351
- Restructuring the document sections to align with the interests of key stakeholder groups – ITCA's, Cybersecurity testing organizations, certification bodies and test laboratories – the revised sections are targeted at the interests and responsibilities of specific stakeholders
 - An expanded section on cybersecurity – this topic was covered briefly in IPRM V1 and provided much more detailed coverage in this new release and the ITCA role in cybersecurity testing and certification is clarified further
 - The requirements tables in Version 1 were reviewed and condensed to eliminate redundancy and non-measurable criteria. The tables were also relocated in the document to align with the applicable sections (removes the need to jump back and forth between sections of interest). The requirements in IPRM V2 are intended to be more easily implementable for third party accreditation and other assessment operations.

Interoperability Process Reference Manual (IPRM)

352 **3.2. Organization of the IPRM**

353

354 The preceding sections provide the necessary background to understand the issues addressed by
355 the IPRM, the SGTCC philosophy in addressing the issues, the objectives of the IPRM in solving
356 the issue and the basic foundation of international standards upon which the IPRM is constructed.

357

358 The IPRM considers these international standards (ISO/IEC Guide 65 and ISO/IEC 17025) as fun-
359 damental foundation elements to be implemented in Smart Grid interoperability testing and certifi-
360 cation programs. The SGTCC has identified other detailed recommendations and requirements
361 that extend beyond the baseline criteria found in the ISO standards. These are addressed in sub-
362 sequent section of the IPRM as follows:

363

- 364 • Section 4 - ITCAs and their implementation of the IPRM
- 365 • Section 5 - Recommendations and requirements for ITCAs beyond those identified in
366 ISO/IEC Guide 65 and ISO/IEC 17025
- 367 • Section 6- Recommendations and requirements specific to Cybersecurity Testing
- 368 • Section 7 - Detailed Tables of Criteria recommended for implementation by ITCA Certifica-
369 tion Bodies and Test Labs

370

371

372

373

374

375

Interoperability Process Reference Manual (IPRM)

4. ITCA Implementation of the IPRM

The SGTCC strongly advocates the implementation of an Interoperability Testing and Certification Authority (ITCA) organization to support each Smart Grid standard.

The implementation of the IPRM by an ITCA is intended to accomplish several goals:

- Increase the buyer's confidence in the purchase of neutral 3rd party certified interoperable products for their organizations over time
- Standardize the testing and certification processes, through a set of best practices, used for all smart grid products
- Provide a basis for an approval process for those organizations following the IPRM to assure the purchasing organizations of quality, audited testing programs. The SGTCC believes that end users purchasing Smart Grid products based on standards will save money and shorten product implementation cycle time by using products that comply with the SGIP TCC Framework.

4.1. *What is an ITCA?*

An Interoperability Testing and Certification Authority (ITCA) is the program management organization providing oversight for testing and certification activities associated with one or more standards or specifications, that takes responsibility to ensure that interoperable products within the scope of the specific ITCA program are brought to market. The ITCA coordinates the participation of certification bodies and test labs for its program.

Interoperability Process Reference Manual (IPRM)

401 An early finding of the SGTCC was that standards that had an associated ITCA engaged in test
402 and certification of products to the standard were more rapidly implemented and adopted by the
403 market place.

404

405 The SGTCC has established the following required practices for ITCAs, certification bodies and
406 test laboratories:

407

- 408 • Certification bodies (CBs) shall be accredited to ISO Guide 65, *General Requirements for*
409 *Bodies Operating Product Certification Systems*
- 410 • Test laboratories shall be accredited to ISO 17025, *General Requirements for the Compe-*
411 *tence of Testing and Calibration Laboratories*
- 412 • The ITCA shall have an agreement with an accrediting organization(s) to assure that Certi-
413 fication Body and Test Lab accreditation is being performed in accordance with the ITCA
414 program scheme.
- 415 • An ITCA shall have a strong relationship with the SSO associated with the standard for the
416 purpose of feedback towards standard improvement and clarification where there may be
417 ambiguities

418

419 The requirements for adherence of ITCAs to these internationally recognized industry standards is
420 consistent with the practices exhibited in other industry programs engaged in testing and certifica-
421 tion activities related to critical infrastructure (e.g. FCC programs for communications networks)
422 and issues impacting personal safety and security (e.g. OSHA NRTL safety programs).

423

424

425

Interoperability Process Reference Manual (IPRM)

4.2. *How does an ITCA implement the IPRM?*

426

427
428 An ITCA begins its implementation of the IPRM by declaring their intent to participate in the pro-
429 gram and implement the IPRM recommendations in their program scheme. This step is formalized
430 by completion of the ITCA Application Form located on the SGTCC Twiki site:

431

432 <http://collaborate.nist.gov/twiki-sggrid/bin/view/SmartGrid/SGTCCIPRMImplementation>

433

434 Submittal of the ITCA Application Form indicates that the ITCA has entered a transitional phase
435 during which time they are actively engaged in integrating the IPRM recommendations in their pro-
436 gram. The SGTCC recognizes that implementation is a significant investment for the ITCA. The
437 SGTCC will recognize those ITCAs that have committed to the IPRM by acknowledging their par-
438 ticipation on the SGTCC TWiki site.

439

440 As an acknowledged participant in IPRM implementation, the ITCA must be able to clearly demon-
441 strate that they are progressing with their implementation activities in a timely manner. The SGTCC
442 retains the right to remove its ITCA program acknowledgement where it concludes that the ITCA is
443 not actively implementing the IPRM and/or fulfilling other obligations necessary to achieve IPRM
444 implementation.

445

446 In the longer term, it is expected that an ITCA will fully implement the IPRM recommendations, uti-
447 lizing certification bodies that have been independently accredited to ISO Guide 65 and test labora-
448 tories that have been independently accredited to ISO 17025. At the time of release of this docu-
449 ment, the SGTCC is actively engaged in dialogue with accreditation organizations to facilitate the
450 availability of these assessment services in 2012, with the key IPRM recommendations integrated
451 into the independent accreditation criteria.

452

Interoperability Process Reference Manual (IPRM)

4.3. Relationship between Accreditation Bodies, ITCAs, Certification Bodies and Test Labs

The diagram below depicts the relationships across the key elements of testing and certification programs in the view of the SGTCC. ITCAs may be structured with subtending certification bodies and test labs dedicated to its mission. Alternatively, the ITCA may serve a dual role, acting itself as the certifying body. The SGTCC recognizes that flexibility is necessary in ITCA structure to accommodate the diverse needs across the many technologies that are a part of the Smart Grid. While that flexibility and any necessary innovation are encouraged by the SGTCC, the one constant required is the need for checks and balances in the process such that certification decisions are made by personnel independent of those developing test data.

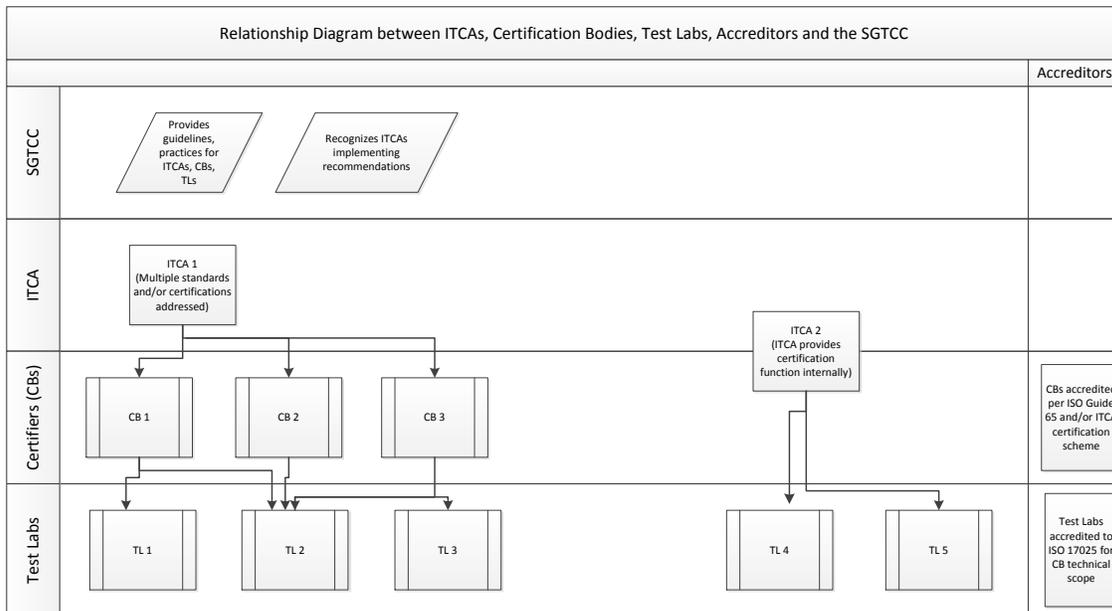

Figure 2 – Relationships between Accreditation Bodies, ITCAs, CBs, TLs, and SGTCC

465

466

Interoperability Process Reference Manual (IPRM)

5. Interoperability and Conformance Test Construction

This section provides requirements, best practices and guidelines for ITCAs in their development and operation of interoperability and conformance testing programs. The recommendations provided in this section were generated based on input from experienced testing organizations that have evolved interoperability and conformance programs through lessons-learned in executing tests for both software and hardware applications.

The recommendations may not apply directly to all testing applications; however, they should be considered for interoperability and conformance test programs as these practices have proven to be valuable in executing a broad cross-section of program types.

Each ITCA should evaluate how these recommendations, observations and practices apply to their specific programs, and incorporate the recommendations into their programs where applicable.

An ITCA SHALL manage the end-to-end processes associated with interoperability testing and certification. It is expected that the ITCA has the appropriate infrastructure in place to support this function. Where a new ITCA is being launched in support of a standard, establishment of the following is recommended:

- Business plan
- Clear governance structure and IPR policy
- Testing lab(s)
- Certification body / bodies

Interoperability Process Reference Manual (IPRM)

494 The requirements in this section, as well as those provided in Section 6 for Cybersecurity and in
495 Section 7 for Certification Bodies and Test Labs SHALL be implemented by the ITCA in its pro-
496 grams to enable product interoperability, cybersecurity and quality testing and certification services.

497

498

499 **5.1. General Test Policies**

500

501 • ITCAs must provide explicit information on the requirements, processes and expectations
502 associated with their program to prepare vendor participants for the certification process.
503 Example information required includes, but is not limited to, eligibility criteria to establish
504 that the program is appropriate for a specific product, how to prepare for certification, and
505 requirements for specific test environments (i.e. GUI applications to access low-level APIs,
506 test scripts, supported browsers, dedicated test hardware, samples, etc.) in order to con-
507 duct testing.

508 • Final Test Reports should include at a minimum:

- 509 ○ Organization(s) that conducted the tests and location(s) where the tests took place
- 510 ○ Test completion dates
- 511 ○ Product name / version / release tested
- 512 ○ Type of tests (i.e. interoperability or conformance)
- 513 ○ Test script version information
- 514 ○ Standards version information
- 515 ○ Technique(s) used for a test including standards and procedures followed
- 516 ○ Test profile used or a list of test cases if a complete test profile is not used
- 517 ○ Test equipment used, and all equipment traceability statements.
- 518 ○ Where interoperable results are claimed, details on the extent, conditions and/or
- 519 limitations in the findings SHALL be fully identified

- 545
- If a certification program limits the length of a certification, this information should be communicated so that product providers and end users are aware of any such expiration in validity. Criteria for expiration is an ITCA business decision, and may be based on factors including but not limited to, standards revisions and product changes.
 - An interoperability testing program shall determine whether or not interoperability has been demonstrated between all products within the scope of the test. The ITCA must not assume conformance testing achieves interoperability unless significant market based historical evidence that their tested products are completely interoperable using conformance based methods. Additionally, such evidence should be thoroughly and formally recorded, for example as collected for ISO Guide 65 surveillance activities – anecdotal information or lack of reported interoperability problems is insufficient. The ITCA or certification body must not declare they have achieved interoperability in the products unless one or both of the above conditions (test reports/data or documented market based evidence) is qualitatively achieved and demonstrated.
 - A certified interoperable product SHALL be conformant to the standard unless full conformance causes interoperability issues. In such cases, the issue should be reported back to and formally recognized by the ITCA and/or the SSO so corrective action can be taken.
 - The level of Interoperability and Conformance testing is always a trade-off between cost and test coverage. It is highly recommended that the ITCA perform a cost-benefit analysis on the degree of coverage associated with the test for both conformance and interoperability against the cost to test. In determining the test coverage, the security and safety concerns along with appropriate NERC / similar requirements should be considered paramount in determining the coverage assessment.
 - Proper test tools produce reliable, repeatable and traceable test results. Such tools require validation processes, test suites, tool documentation, test reports, calibration certificates and other relevant artifacts. The validation of the test tools must be performed against a

Interoperability Process Reference Manual (IPRM)

546 defined sample of software and / or hardware implementations under test. Refer to ISO /
547 IEC 17025 for more detail on the use of qualified and calibrated test tools³.

548

549 **5.2. Test Suite Specification (TSS)**

550

551 A TSS consists of a suite of tests, categorized into logical functional areas, such as use cases or
552 well-defined features. Each test suite consists of many related test cases corresponding to a par-
553 ticular feature set or use case. A test profile evaluates a subset of a TSS and are used to target
554 specific areas of product interoperability.

555

556 • A common TSS should be established when one or more test labs are deployed to test the
557 same standard and / or profile. If unique test procedures are required to support a test
558 suite, then they should also be defined.

559

• The TSS should be test tool agnostic.

560

• The TSS should be subject to revision control including revision history, revision number-
561 ing, and a defect / expansion management process. The TSS should clearly identify the
562 test purpose, references, resource requirements, test setup, procedures, observable re-
563 sults and possible problems / lessons learned with the test approach. Observables should
564 clearly identify pass / fail / indeterminate requirements and informational elements.

565

• The TSS should clearly define any conventions that will be required to achieve interopera-
566 bility.

567

• The TSS should restrict cardinality and define the exact attributes and associations re-
568 quired for interoperability.

569

• The TSS should remove or clarify all ambiguities and any areas of the standard that may
570 be interpreted differently between two or more interoperable systems.

³ Recognize that validation and calibration of test tools is a function of the type of test tool being used. For protocol analyzers or frequency measurements calibration is important and defined. For software applications the validation is against the intent in the specification defining the application behaviors. Calibration as such may not apply

Interoperability Process Reference Manual (IPRM)

- 571 • The TSS should be a standard and managed as such by an ITCA or SSO. The documen-
572 tation should include scope, date of issue, revision, change control, and methods to feed-
573 back implementer's results.
- 574 • Where applicable, the TSS should specify an approach to validate data and data structures
575 contained in, or produced by, the test.
- 576 • Test cases should have clear mappings to feature-sets, use-cases, and requirements.
- 577 • An interoperability testing program SHALL determine whether or not interoperability has
578 been demonstrated between all products within the scope of the test. The TSS MUST en-
579 sure all areas of the interoperability and conformance testing are sufficiently defined and
580 documented such that the test can be repeated.
- 581 • The TSS MUST define the test data required to execute the test cases. The TSS should
582 define any test stub required to execute messages that will generate negative responses.
- 583 • The TSS should identify interoperability issues arising from ambiguities in the standard,
584 and make recommendations to the appropriate SSO for improvements in the specification
585 for the standard to prevent those interoperability issues.
- 586

587 **5.3. Attributes of a Test Profile in lieu of complete TSS**

- 588
- 589 • MUST be a subset of the TSS
- 590 • Specifies mandatory and optional elements
- 591 • Specifies all restrictions
- 592 • Cannot add to the standard, but can only restrict the standard
- 593 • Define the type of profile (i.e. message, model or implementation) and provide a name for
594 the profile that clearly defines the objective / scope of the profile and the use-cases it is
595 designed to test
- 596 • Is a companion standard or is submitted to the SSO for progression as a companion
597 standard

5.4. ITCA Technical Program Design Recommendations

This section is taken from the Technical Requirements tables used in IPRM Version 1.

Tech-x	Technical Program Design Requirements Description
Tech-1	The ITCA MUST specify in the TSS those features that are mandatory, and those features that are optional.
Tech-2	The ITCA MUST require and enforce that vendors declare the optional features implemented in a product.
Tech-3	The ITCA SHALL require that implementations of optional features be tested and certified for conformance and interoperability. Furthermore, the ITCA should define common test cases for optional features to be used by all test labs.
Tech-4	An ITCA SHALL define the record handling and retention requirements to be followed by the TL and CB functions, consistent with requirements of ISO 17025 and ISO Guide 65. The ISO standards require a record handling/retention policy – the ITCA should define and implement specific details/durations regarding record handling and retention.
Tech-5	The ITCA SHALL specify the conditions under which it will allow for sub-component (e.g., previously certified hardware modules used in developing final products, previously certified software components with well-defined interfaces and dependencies etc.) inheritance in development of final products. However, it is the ITCAs responsibility to ensure that interoperability is maintained.
Tech-6	The ITCA SHALL maintain a controlled list of compatible sub-components that can be inherited to build final products. This might include specifying compatible feature-sets.

Interoperability Process Reference Manual (IPRM)

Tech-7	When supporting products composed of sub-components, the ITCA SHALL define the set of additional tests necessary to ensure interoperability (e.g. integration testing, final performance testing, etc.)
Tech-8	The ITCA SHALL implement a Compliant Portion Description (CPD) ⁴ to be used as a guide for assembling a product based on compatible sub-components.
Tech-9	The ITCA SHALL have an explicit process in place to assess necessity of re-certification against subsequent release versions of a specification, including security.
Tech-10	The ITCA SHALL define the level of re-certification required for subsequent release versions of a specification.
Tech-11	The ITCA SHALL define a mechanism to identify the latest version of a previously certified product or system implementation. This is important in cases where a previously certified product or system has been upgraded to a different version.
Tech-12	The ITCA SHALL have a mechanism to enforce version control rules such that each product certification clearly identifies the SSO document and version to which product is certified.
Tech-13	The testing and certification program SHALL have common well-defined standardized test cases. These test cases should be defined in an open, consensus-driven fashion. These test cases will be used by all test labs approved by the ITCA.
Tech-14	There SHALL be a defined correlation between implementations and required testing, commonly called a Proforma Implementation Conformance Statement (PICS). ⁵
Tech-15	The testing and certification program SHALL maintain a current and upcoming list of applicable test cases to be called a Test Case Reference List.
Tech-16	There SHALL be a Test Plan derived from the Test Case Reference List and used by all authorized test labs. Tests SHALL be identified using the test plan.
Tech-17	The testing and certification program SHALL require that a static conformance re-

⁴ See Glossary of Terms for definition and further explanation of CPD

⁵ PICS can be referred as both Protocol Implementation Conformance Statement and Profile Implementation Conformance Statement. Proforma is being used in this requirement to reference both concepts.

Interoperability Process Reference Manual (IPRM)

	view ⁶ take place prior to testing a product. This review is used to determine the applicability of the test program requirements relative to the features and functionality of the product under test to assure the test plan addresses all applicable requirements.
Tech-18	The testing and certification program SHALL implement validated test tools. Golden reference test equipment may be utilized where appropriate.
Tech-19	The TSS SHALL be subject to revision control, including revision history, revision numbering, and a defect and expansion management process. The TSS should clearly identify the test purpose, references, resource requirements, test setup, procedures, observable results and possible problems / lessons learned with the test approach. Observables should clearly identify pass / fail / indeterminate requirements and informational elements.
Tech-20	The testing and certification program SHALL ensure that defined product test cases cover application profiles for specific feature sets and functions defined by the specific application profile, and implement interoperability evaluation within that application profile.
Tech-21	Where practicable, the testing and certification program SHALL ensure that defined product test cases cover all feature sets and functions.
Tech-22	The testing and certification program SHALL ensure that defined product use cases are covered in application profiles. Interoperability testing and evaluation SHALL be implemented within those application profiles.
Tech-23	The testing and certification program SHALL classify common or major market products according to their application profiles, and include them as part of an interoperability evaluation for those specific profiles. The evaluation SHALL make use of test profiles correlated to those specific applications. ⁷

⁶ See Glossary of Terms for the definition and explanation of a static conformance review.

⁷ Interoperability testing is tied to market realities. Hence the testing and certification program needs to have a mechanism to adopt representative market products as an integral part of interoperability testing.

Interoperability Process Reference Manual (IPRM)

Tech-24	The testing and certification program SHALL ensure that venues are provided for multi-vendor and multi-product communication and interchange evaluations (e.g. “plug fests”). This program may be optional for ITCA’s correlated to standards resulting in application interfaces and not a physical product
Tech-25	Prototyping of draft standards or major revisions SHALL be supported via multi-vendor / multi-product testing. The ITCA SHALL solicit for the prototyping of draft standards or major revisions, and organize multi-vendor / multi-product testing. It is recommended that the prototyping take place in the late stages of standards development in order to verify the correctness of the standard, verify the test suites and verify that the anticipated interoperability or conformance testing is debugged.
Tech-26	ITCA’s SHALL use reference test tools ⁸ where appropriate to the technology under test (hardware and/or software) to provide a consistent and replicable approach in generating test results across ITCA test labs. Successful testing programs assure that there is a known reference or constant to which the system is evaluated against the desired metrics to determine conformance.
Tech-27	ITCA program tests that are performed across multiple test facilities SHALL implement processes to assure they are each measuring against a common known reference and achieving repeatable results regardless of location.
Tech-28	The ITCA SHOULD have a process to select a minimum of two distinct reference implementations as golden implementations or golden units. The selection is usually based on the results of the interoperability testing. All other implementations SHOULD be tested against these golden implementations. ⁹
Tech-29	The golden implementations or golden units SHOULD be clearly associated with

⁸ A number of terms are used in describing reference test tools such as “common test harness”, “golden reference test equipment”, and “golden reference test products”. Generally, these each represent test tools available to a test lab or end user to provide a consistent baseline test either as a standalone implementation or in concert with the many other types of test tools available.

⁹ The industry prefers three golden units for product testing, but the minimum number of golden units shall be no less than two golden units.

Interoperability Process Reference Manual (IPRM)

	each version of the standard. Each golden unit is a snap shot (instantiation) of each version of the standard.
Tech-30	If an ITCA Certification Program involves multiple Smart Grid systems, then the Program Requirements SHALL support end-to-end testing of Smart Grid systems involving multiple product implementations to the fullest extent possible.
Tech-31	An ITCA SHALL involve all relevant parties to define various business logic models for the end-to-end system testing, and make scenarios and test harness systems available for testing.
Tech-32	The testing and certification program SHALL ensure that when functional performance requirements are defined in an application profile, the performance test profile(s) SHALL be designed to implement test cases for evaluating these requirements.
Tech-33	The ITCA SHALL ensure that test tools have a complete mandatory feature-set coverage of a standard. In cases where two or more implementations of optional features are available, the ITCA SHALL incorporate those feature-sets in the test tool. ¹⁰
Tech-34	The ITCA SHALL define procedures and processes to validate the use of test tools and reference implementations
Tech-35	ITCA shall develop criteria for surveillance to be carried out by its certification bodies.

602

603 **5.5. Program and Field Experience Feedback**

604

605 Successful achievement of interoperability requires a well-communicated feedback process across
 606 multiple stakeholders – the ITCA, its testing and certification bodies, standards bodies, end users
 607 and vendors. Such feedback loops are essential in the continuous improvement of test programs
 608 and the standards upon which they are based. This feedback provides greatest value when it is

¹⁰ Effective test tools need to be able to test all features and functions of a standard. Some features of a standard may never be supported by certain products; however when a standard is published, the industry is free to implement optional feature set in addition to the mandatory set; lack of testing capability of optional feature sets hinders interoperable feature set introduction. Normally, validated test tools have implementations of all features, including optional ones as a condition for the tool validation.

Interoperability Process Reference Manual (IPRM)

609 multi-directional, and the ITCA is ideally positioned to manage this information exchange that can
610 help strengthen the base standards and test programs through lessons learned both in the lab and
611 in the field.

612

613 An ITCA test program is based on a standard. The ITCA's development of its test methodology
614 provides the opportunity to identify gaps and other issues requiring clarification that should be
615 communicated to the standards body to improve future releases. Similarly, the experiences and
616 lessons learned by the ITCA testing labs can identify criteria in a standard that may present unfore-
617 seen difficulties for products to achieve or items not tightly defined that might lead to interpretive
618 differences – again, communicating to the standards body can lead to future improvements.

619

620 Perhaps the most critical feedback to be gathered and communicated comes from the end users
621 and product vendors. They can provide definitive feedback on any field interoperability problems
622 associated with “certified” products, necessitating the ITCA and test labs to revisit their test pro-
623 grams to identify any gaps or opportunities to tighten the testing process to help mitigate these in-
624 teroperability issues in a lab environment, well before products are deployed. This process may
625 also necessitate the ITCA and its certification body reviewing existing “certified” products to deter-
626 mine if any additional testing and analysis is needed to confidently maintain the designation of be-
627 ing certified.

628

629 An ITCA program SHALL include a documented surveillance and continuous feedback process to
630 address these potential issues and enhance the interoperability of deployed products.

631

632

Interoperability Process Reference Manual (IPRM)

633 **6. Cybersecurity Testing**

634

635 The SGTCC has collaborated with the SGIP's Cybersecurity Working Group (CSWG), particularly
636 the CSWG testing and certification sub-working group that has contributed its expertise in prepar-
637 ing this section of the IPRM. Cybersecurity testing and certification issues and practices are a col-
638 laborative effort between the SGTCC and CSWG in supporting ITCAs in their implementation of the
639 IPRM recommendations for cybersecurity testing.

640

641 ITCAs are first and foremost responsible for ensuring and certifying that products developed using
642 a specific standard are interoperable. Customers for products, their system integrators and ven-
643 dors and other organizations such as NERC have primary responsibility for cybersecurity of result-
644 ing systems that ITCA certified products become a part of. To the extent that cybersecurity speci-
645 fications and specific controls are incorporated in a standard and in certification profiles of that
646 standard, the ITCA is responsible for validating the conformance and interoperability of cybersecu-
647 rity functions in the same way as other functions in the profile. The ITCA is not responsible for cer-
648 tifying or ensuring that products it certifies are cyber secure, but it is responsible to ensure that cy-
649 bersecurity functionality exists as specified in a standard and certification profile. This does not
650 prevent an ITCA from taking on responsibility for security testing and, should it do so, this section
651 provides guidance in that respect.

652

653 **6.1. Introduction**

654 Most product vendors make a claim as to functionality and/or offered cybersecurity controls. Or-
655 ganizations need to have a minimum level of assurance that a product's stated function and cyber-
656 security claim is valid. Confidence in a product's cybersecurity can be based on an impartial cy-
657 bersecurity evaluation, which includes an analysis of the product and the testing of the product for

Interoperability Process Reference Manual (IPRM)

658 conformance to a set of cybersecurity requirements and controls. The use of consistent standard-
659 ized cybersecurity evaluation criteria and methodologies contributes to the repeatability and objec-
660 tivity of the results. Cybersecurity testing should be performed in coordination with interoperability
661 tests but because of the difference in focus and expertise of the two types of testing, they are typi-
662 cally done by separate test labs. As functionality is developed to enable interoperability, new poten-
663 tial vulnerabilities could be discovered. By ensuring cybersecurity testing is coordinated with in-
664 teroperability tests the following objectives are met:

- 665 • Uncover design, implementation and operational flaws that could allow the violation of cy-
666 bersecurity requirements and controls;
- 667 • Determine the adequacy of cybersecurity mechanisms, assurances and other properties to
668 enforce the cybersecurity requirements and controls;
- 669 • Assess the degree of consistency between the cybersecurity requirements and controls
670 and their implementation;
- 671 • Identify and locate loopholes that can cause loss of important information, function, or al-
672 low unauthorized access; and
- 673 • Identify the cyber security functionality that could impact the interoperability of components
674 and systems.

675 **6.2. Cybersecurity Concepts**

676 The primary objective of cybersecurity testing is to validate the cybersecurity claims. Testing will
677 determine if the product functions as intended and conforms to a defined set of cybersecurity re-
678 quirements. At a high level, this means providing confidentiality, integrity (authenticity and non-
679 repudiation), and availability for the information stored on the product and system into which the
680 product is integrated. To the extent that specific requirements and specifications are included in a
681 standard profile tested by an ITCA, normal conformance and interoperability tests will validate that
682 the cybersecurity requirements have been met. However, the normal certification testing of an

Interoperability Process Reference Manual (IPRM)

683 ITCA is not expected to establish the vulnerability characteristics of the implementation nor assure
684 that implementations cannot be "hacked".

685 **6.3. Cybersecurity Testing Environment**

686 A critical part of conducting cybersecurity testing is the environment in which the products are test-
687 ed. Products should be tested in an environment that closely simulates the intended implementa-
688 tion of the product. Cybersecurity testing should conform to identified environmental standards and
689 specifications. An internal cybersecurity policy should be developed for the product being tested
690 which provides the cybersecurity rules under which an implementation or cybersecurity testing en-
691 vironment must operate. In order to understand the security of an implementation being tested, the
692 rules and assumptions about how the implementation must operate need to be specified in particu-
693 lar for mitigations and controls outside the boundary of the implementation. Environmental condi-
694 tions, particularly when outside the normal operating conditions of a component or system, could
695 cause a potential critical cybersecurity breach, so they need to be considered during testing. For
696 example, in some extreme temperatures, humidity and radiations, authentication devices can fail
697 even when these conditions are not maliciously induced.

698 **6.4. Cybersecurity Testing Types and Frameworks**

699 The type of cybersecurity tests conducted on a product will depend on the type of product, its func-
700 tionality, operating environment, and both functional and non-functional cybersecurity require-
701 ments. When intertwined with interoperability testing, cybersecurity specific test methodologies
702 should be documented. The interoperability testing results should remain intact and verified after
703 security fixes are applied to address issues found during cybersecurity testing. Different testing
704 methodologies are used to determine attributes (interoperability, conformance, usability, security,
705 etc.) of an implementation being tested. Multiple types of testing techniques should be used, in-
706 cluding manual review, fuzz testing, static analysis, dynamic analysis, and penetration testing.

707 In general, Smart Grid security testing/assessment approaches can be broken into the following
708 major categories:

Interoperability Process Reference Manual (IPRM)

709 • **Security Conformance/Certification Testing** is usually initiated by each vendor, to verify
710 that a vendor product meets an industry established level of security, and tested by inde-
711 pendent third-party labs using the same testing procedures that are pass/fail in nature.
712 Results of these tests are often published and used in vendor marketing campaigns. For
713 security functions and controls that are included in the certification profile of an ITCA, the
714 normal conformance and interoperability testing of those features and functions adequately
715 conform to the certification profile.

716 • **Security Interoperability Testing** measures the interoperability of security components
717 between devices and systems from different vendors.

718 Security Conformance/Certification Testing and Security Interoperability Testing are categories that
719 would typically be within the purview of an ITCA. The following other major categories of Smart
720 Grid security testing/assessment would typically be the responsibility of other stakeholders, how-
721 ever ITCAs should maintain awareness of these other approaches as they relate to their program
722 offerings. Further, should an ITCA choose to become a cybersecurity certification authority as a
723 complement to its interoperability authority status, it will need to address these security assess-
724 ment and testing categories.

725 • **Security Architecture Review** is a form of paper and pencil exercise to discuss the con-
726 figurations and security posture of a particular system, which often includes not only that
727 system but how that system is connected to other systems and devices. This type of test
728 can also include policy review and how it affects the organization and systems the policies
729 govern.

730 • **Vulnerability Assessments** is a form of assessment that uses tools to find known vulner-
731 abilities in systems by analyzing the system version, retrieving its configuration, and com-
732 paring them to the vulnerability databases leveraged by the tools. Utility security depart-
733 ments or a contracted specialized security firm they hire usually perform this type of as-
734 sessment.

Interoperability Process Reference Manual (IPRM)

- 735 • **Penetration Testing** is a specialized form of assessment where the testing team takes on
736 the role of the attacker and tries to find and exploit vulnerabilities in systems and devices.
737 Testers use the same methodology that attackers often use to identify vulnerabilities in the
738 system. Once a vulnerability is found, the testers attempt to exploit the flaw to gain a foot-
739 hold in the system and begin the process again to discover additional, lower level vulnera-
740 bilities that weren't previously exposed. Penetration testing is distinguished from vulnera-
741 bility assessments by the fact it tests the depth of vulnerabilities instead of simply breadth,
742 focus on discovering both known and unknown vulnerabilities, and provide the testing
743 team with a better understanding of a vulnerability's risk to the business.
- 744 • **Security Code Review** is a form of assessment performed to identify security flaws in the
745 source code of systems and devices. Vendors usually perform this type of assessment
746 since system source code is not usually provided to the customer. However, in some in-
747 stances a vendor may provide the source code to a third-party assessment laboratory, if a
748 non-disclosure agreement is in place.
- 749 • **Compliance Review** is a form of assessment that focuses on the existence and execution
750 of security policy. This can be performed to fulfill a formal regulatory requirement such as
751 NERC CIP or an informal, internal assessment to determine compliance with such guid-
752 ance documents as the NISTIR 7628, security profiles from the Advanced Security Accel-
753 eration Project (ASAP-SG), or other non-regulatory documents.
- 754 • **Verification and Validation (V&V) Testing** or **Final Acceptance Testing (FAT)** is a final
755 step of an electric utilities' purchasing and deployment process, to confirm that the system
756 meets business requirements and fulfills its intended purpose. This type of assessment
757 can include one or more of the assessments listed above, including penetration testing.

758 Each cybersecurity testing laboratory should follow a documented cybersecurity testing framework
759 or methodology to perform all of their cybersecurity testing. Some of the most common cybersecu-
760 rity testing frameworks are:

Interoperability Process Reference Manual (IPRM)

- 761 • **The Common Criteria for Information Technology Security Evaluation (Common Cri-**
762 **teria or CC)** is an international standard (ISO/IEC 15408) for computer security certifica-
763 tion. Common Criteria is a framework in which computer system users can specify their
764 security functional and assurance requirements, vendors can then implement and/or make
765 claims about the security attributes of their products, and testing laboratories can evaluate
766 the products to determine if they actually meet the claims.
767 <http://www.commoncriteriaportal.org/>.
768
- 769 • **The Information Systems Security Assessment Framework (ISSAF)** testing methodol-
770 ogy is designed to evaluate network, system and application controls.
771 <http://www.oissg.org/index.php/issaf>
772
- 773 • **NIST Special Publication 800-53A, *Guide for Assessing the Security Controls in***
774 ***Federal Information Systems and Organizations*** is written to facilitate security control
775 assessments conducted within an effective risk management framework. Special Publica-
776 tion 800-53A is a companion guideline to Special Publication 800-53, *Recommended Se-*
777 *curity Controls for Federal Information Systems and Organizations*.
778 <http://csrc.nist.gov/publications/nistpubs/800-53A-rev1/sp800-53A-rev1-final.pdf>.
- 779 • **The Open Source Security Testing Methodology Manual (OSSTMM)** provides a scien-
780 tific methodology for the accurate characterization of operational security (OpSec) through
781 examination and correlation of test results in a consistent and reliable way. This manual is
782 adaptable to almost any audit type, including penetration tests, ethical hacking, security
783 testing, vulnerability testing, red-teaming, blue-teaming, and so forth. It is written as a se-
784 curity research document and is designed for factual security verification and presentation
785 of metrics on a professional level.
786 <http://www.isecom.org/mirror/OSSTMM.3.pdf>

Interoperability Process Reference Manual (IPRM)

- 787 • **The Penetration Testing Execution Standard (PTES)** is a standard designed to provide
788 both businesses and security service providers with a common language and scope for
789 performing penetration testing. The standard defines a baseline for the minimum effort re-
790 quired for a basic pentest, and includes several higher "levels" to provide more compre-
791 hensive activities for organizations with higher security needs.
792 http://www.pentest-standard.org/index.php/PTES_Technical_Guidelines
- 793 • **NIST SP800-115, *Technical Guide to Information Security Testing and Assessment*** is
794 a guide to the basic technical aspects of conducting information security assessments. It
795 presents technical testing and examination methods and techniques that an organization
796 might use as part of an assessment, and offers insights to assessors on their execution
797 and the potential impact they may have on systems and networks.
798 <http://csrc.nist.gov/publications/nistpubs/800-115/SP800-115.pdf>.
- 799 • **NIST SP800-142, *Practical Combinatorial Testing*** is a method that can reduce cost and
800 increase the effectiveness of software testing for many applications by testing combina-
801 tions of parameters that provides highly effective fault detection.
802 <http://csrc.nist.gov/groups/SNS/acts/documents/SP800-142-101006.pdf>.

6.5. ***Additional Cybersecurity Testing Laboratory Best Practices to Consider***

803 Along with the cybersecurity testing concepts, environments, and framework considerations de-
804 scribed above, the following provides additional cybersecurity testing best practices for a cyberse-
805 curity testing laboratory to consider:
806
807

- 808 • The cybersecurity test team members should subscribe to a specific code of ethics. An
809 organization like the National Board of Information Security Examiners (NBISE),
810 <https://www.nbise.org>, helps to validate hands-on skills and knowledge in order to reliably
811 predict an individual's future performance and aptitude for cybersecurity.

Interoperability Process Reference Manual (IPRM)

- 812 • A risk and threat analysis should be provided for the item to be tested. A risk and threat
813 analysis provides information to the test team about actions that may be harmful to an im-
814 plementation and the sources of the actions. In order to understand the security of the im-
815 plementation being tested, both the threats an implementation is expected to address as
816 well as the threats that are not addressed need to be known. Particularly threats that are
817 intended to be addressed by mitigations external to the implementation need to be docu-
818 mented to properly scope and bound the test to be performed.

- 819 • Existing cybersecurity test programs should be leveraged when possible. Integrating exist-
820 ing cybersecurity test programs into a cybersecurity testing program allows for the exper-
821 tise and experience from other cybersecurity testing domains to be applied. However, un-
822 derstanding the limits of existing cybersecurity testing programs is required in order to in-
823 tegrate those programs appropriately. By leveraging existing cybersecurity testing pro-
824 grams, it may reduce the time and cost of the testing process.

- 825 • Component cybersecurity testing should be included in cybersecurity test programs when
826 possible. When a software or firmware component contains vulnerabilities and is reused
827 throughout a product line, those vulnerabilities could be within multiple products. Testing at
828 the component level ensures that the layered cybersecurity within a product continues to
829 protect the information and processing. Components often require re-interoperability test-
830 ing when used in a different configuration to ensure proper setup and use.

- 831 • Cybersecurity testing programs should ensure they align with the business and technical
832 requirements for the enterprise, unit, product, etc. When cybersecurity testing programs
833 align with business, system, and technical requirements, risk can be limited and the prod-
834 uct will have cybersecurity designed into the components and systems, so it can be part of
835 the core testing and not an add-on “feature” to be tested.

Interoperability Process Reference Manual (IPRM)

836 **6.6. Role of the Cybersecurity Testing Providers**

837 Cybersecurity testing is typically conducted by information system developers, system integrators,
838 certification agents, information system owners, auditors, inspectors general, and the information
839 security staffs. Cybersecurity testing services, whether provided by an element within the custom-
840 er's organization or a contracted public or private sector entity should demonstrate a variety of dif-
841 ferent capabilities. The cybersecurity testing provider should have a management structure that
842 provides the framework for testing teams to conduct effective cybersecurity testing. The cybersecu-
843 rity testing provider should be able to perform administrative functions to support the testing teams,
844 protect the information received from the customer, and develop and implement standard proce-
845 dures to ensure that all testing teams provide consistent, reliable and repeatable testing services.
846 Cybersecurity testing providers assemble appropriate individuals to make up a testing team. The
847 team members that work together to prepare for, conduct, and document the findings of the testing.
848 Each team is made up of individuals that should collectively have the knowledge, skills, and abili-
849 ties to conduct the cybersecurity testing.

850

851 Organizational management capability for a cybersecurity testing provider is the implementation of
852 a management system that sufficiently enables a service provider to manage, plan, conduct, and
853 assure quality of cybersecurity testing services. The cybersecurity testing provider should have an
854 operational and management system in place in order to effectively manage and conduct cyberse-
855 curity testing. The management system framework should include: (i) maintaining independence to
856 prevent a conflict of interest when conducting the cybersecurity testing; (ii) implementing an effec-
857 tive management structure that provides both technical oversight and administrative support; (iii)
858 providing the resources to select an effective testing team with the knowledge, skills, and abilities
859 to conduct the testing based on the customer's product's cybersecurity claims; (iv) protecting cus-
860 tomer information collected during the cybersecurity testing process; and (v) implementing or creat-
861 ing tools, templates, and standard cybersecurity testing procedures to ensure each testing team
862 provides consistent service. Customers should be confident that the cybersecurity testing provid-

Interoperability Process Reference Manual (IPRM)

863 er's cybersecurity testing teams have the knowledge, experience, and resources to conduct an
864 effective cybersecurity test.

865

866 **6.7. Cyber Security**

867 The Cyber Security section outlines the requirements which SHALL be used by the ITCA to
868 validate the security-related components of the interoperability testing program.

869

Sec-x	Cyber Security Improvements Process
	Requirements Description
Sec-1	The ITCA SHALL define the procedures and processes which will be used to validate interoperability cyber security functions and controls incorporated in the ITCA standard and certification profile..
Sec-2	The testing and certification program SHALL ensure that defined cyber security functional performance requirements are evaluated with specific test cases in the TSS.
Sec-3	Where applicable, the ITCA SHALL have a process in place to select and implement a Digital Certificate Issuance mechanism that may include the election of a Certificate Authority. The energy service providers can use this certificate for authentication that a given product has actually been certified. ¹¹
Sec-4	The ITCA SHALL be responsible for certificate management including issuance, maintenance and policing. The ITCA can choose to outsource this responsibility as long as they remain responsible for the interoperable outcome.
Sec-5	The ITCA SHALL implement a process to qualify testing personnel at an appropriate level for their cyber security test training and ex-

¹¹ Optional for ITCAs that result in interfaces and not result a physical product.

Interoperability Process Reference Manual (IPRM)

	perience.
Sec-6	ITCA SHALL document existing security programs and standards which have been used to develop specific security testing, if any.
Sec-7	The ITCA SHALL ensure that processes are in place to incorporate component-based cyber security concepts in the testing program.
Sec-8	The ITCA SHALL ensure that the testing laboratories have and maintain hardware, software, other equipment and facilities necessary for performing specified cyber security tests.

870

871

872

873

Interoperability Process Reference Manual (IPRM)

874 **7. Interoperability Certification Body and Test Labora-** 875 **tory Requirements**

876

877 The ITCA SHALL provide oversight and program requirements enforcement for the Interoperability
878 Testing Laboratories and Certification Bodies in its programs responsible for the implementation of
879 testing and certification activities associated with specified standards. The ITCA is also expected to
880 cooperate with relevant SSOs and user groups for continuous improvement of the program and the
881 standard being addressed.

882

883 Certification Bodies and Test Laboratories are required to be third party accredited to ISO/IEC
884 Guide 65 and ISO/IEC 17025 respectively. These accreditations are attained through assessment
885 by independent accrediting organizations. This section of the IPRM provides additional and sup-
886 plemental requirements for the use of independent accreditors in assuring that ITCA program spec-
887 ifications for their certification bodies and test labs are clearly defined and communicated, and for
888 use in assessing these organizations for their role supporting ITCAs.

889

890 ***7.1. Requirements for Certification Bodies and Test Laborato-*** 891 ***ries***

892 The requirements are comprised of three major categories which will be required by the
893 ITCA to effectively manage the testing and certification functions of their organization.

894 Note: Many of the below items are more formally defined in the ISO 65 and 17025 stand-
895 ards.

896

897 The three major categories are:

- 898 • Governance
- 899 • Lab Qualification
- 900 • Improvement

Interoperability Process Reference Manual (IPRM)

901
902
903
904
905
906

The IPRM requirements are written with the key word “SHALL”. However, depending on the ITCA program and relevant standard under consideration, some requirements may not be applicable for all situations.

907 **7.2. Governance**

908 Governance defines the structures, policies, rules and regulations associated with the
909 ITCA certification program. The following list of Interoperability Governance Process Re-
910 quirements provided in Table 1 SHALL be considered governance process requirements
911 for managing the interoperability testing and certification programs.

912
913

Govern-x	Interoperability Governance Process
	Requirement Description
Gov-1	An ITCA Certification Program SHALL clearly identify the Standard(s) to which testing or certifications are assessed. The ITCA SHALL provide oversight to provide confidence that implementations of Standard(s) in certified products are indeed interoperable.
Gov-2	If an ITCA permits first party testing, the ITCA SHALL clearly define the circumstances under which such testing may be submitted to a certification body and the duties of the certification body in determining the suitability of first party test data.
Gov-3	If an ITCA requires third party testing, the ITCA SHALL clearly identify the circumstances under which such testing SHALL be

Interoperability Process Reference Manual (IPRM)

	submitted to a certification body and the duties of the certification body in reviewing the third party test data.
Gov-4	The ITCA SHALL define a corrective process for resolving reported interoperability problems (e.g. in the field or as part of the test) for products for which they are responsible. ¹² Further, it SHALL implement preventative processes to avoid recurrence of such problems. A problem may be associated with the specification, the test processes and procedures or the test data.
Gov-5	The ITCA SHALL define roles, responsibilities, and resource elements of the interoperability program in documented Certification Program requirements..
Gov-6	The ITCA SHALL specify method(s) for reporting issues to appropriate parties for resolving certification difficulties (vague or inconsistent specifications or test methods, incompatibility with similarly certified products, etc.).
Gov-7	The ITCA SHALL maintain a certified product and systems list. This list SHALL be publicly available.
Gov-8	The ITCA SHALL maintain a test case reference and modification history list. ¹³
Gov-9	Test Suite Specifications (TSS) ¹⁴ used for interoperability or conformance testing SHALL be managed in a well-defined, open and formal manner with change control.
Gov-10	A common TSS SHALL be established when multiple test labs are deployed to test the same standard and / or profile. If com-

¹² The ITCA should use best efforts in contacting a standards body with respect to a specification; however, it is not their responsibility to resolve issues with the specification.

¹³ See Glossary of Terms for definition and explanation of the test case reference list.

¹⁴ See Glossary of Terms for definition and explanation of the TSS.

Interoperability Process Reference Manual (IPRM)

	mon unique test procedures are required to support this test suite, then they SHALL also be defined. The TSS should be test tool agnostic.
Gov-11	All certification bodies operating under the ITCA Certification Program SHALL be accredited as meeting ISO/IEC Guide 65. The accreditation scope SHALL include the International Classification for Standards (ICS) Codes applicable to the technologies for which certification activities are performed. Accreditation SHALL be by an accreditation body that is signatory, in good standing, to the International Accreditation Forum (IAF) multilateral agreement for "Product."
Gov-12	If an ITCA has multiple testing laboratories and certifying bodies, processes SHALL be in place to avoid quality differences and assure repeatable testing between the laboratories.
Gov-13	The ITCA SHALL ensure that the test labs and certification bodies maintain their accreditation for participation in the Certification Program.-

914

915

916

917

Interoperability Process Reference Manual (IPRM)

918

919

920 **7.3. Lab Qualification**

921 Lab qualification defines the requirements in Table 2 that SHALL be applied by ITCAs
922 when recognizing testing laboratories. It should be noted that additional requirements are
923 further detailed in ISO 17025.

924

Lab-x	Interoperability Lab Qualification Process
	Requirement Description
Lab-1	In selecting test organizations, the ITCA SHALL have uniform and transparent procedures for evaluating test labs.
Lab-2	The ITCA SHALL define requirements to qualify the personnel involved in the certification and testing processes.
Lab-3	The ITCA SHALL require that its test labs be accredited to ISO 17025. The accreditation scope SHALL include the specific standards or specifications against which testing may be performed. Accreditation SHALL be by an accreditation body that is (a) a signatory, in good standing, to the International Laboratory Accreditation Cooperation (ILAC) mutual recognition arrangement; or (b) recognized under the (US) National Cooperation for Laboratory Accreditation (NACLA).

925

926

927

928

929

Interoperability Process Reference Manual (IPRM)

930 **7.4. Improvements**

931 The Improvements section outlines the controls that will need to be in place to support the
932 interoperability testing processes.

933

Improv-x	Interoperability Improvements Process Requirements Description
Improv-1	The ITCA SHALL implement monitoring and auditing programs to ensure adherence to its policies. This is in the ISO 65 document.
Improv-2	The ITCA SHALL establish a checklist for the auditing of the appointed evaluation laboratories.
Improv-3	The ITCA SHALL periodically audit the laboratories at appropriate intervals to ensure laboratories uphold necessary capabilities.
Improv-4	The ITCA SHALL establish an auditing procedure and implement audits to verify that product interoperability is maintained after the product passes the testing and certification programs and enters the market.
Improv-5	The ITCA SHALL have processes in place, including corrective and preventative actions, which results in continual improvement of their testing and certification programs.
Improv-6	The ITCA SHALL be in constant communication with the standards writing committees to create a feedback loop. For example, the ITCA should define a process to communicate the TSS test results back to the SSOs and stakeholders.
Improv-7	The ITCA SHALL provide a forum for feedback to be received from a stakeholder, interested business party and use case in order to improve its interoperability best practices.

Interoperability Process Reference Manual (IPRM)

Improv-8	It is preferred that ITCAs have a method for actively soliciting interoperability feedback on implementations of the standard in order to achieve some level of customer and user-community satisfaction on that feedback.

934

Interoperability Process Reference Manual (IPRM)

935 **8. References**

936

937 **NIST Framework and Roadmap for Smart Grid Interoperability Standards**

938 **ISO 17000 - Conformity Assessment** - Vocabulary and general principles

939 **ISO 17011 - Conformity Assessment** - General requirements for accreditation bodies accrediting
940 conformity assessment bodies

941 **ISO 17025** - General requirements for the competence of testing and calibration laboratories

942 **ISO Guide 65** - General requirements for bodies operating product certification systems

943 **ISO Guide 67 - Conformity assessment** - Fundamentals of product certification

944

Interoperability Process Reference Manual (IPRM)

945 **9. Glossary of Terms**

946 **Accrediting Body** – Organization that formally evaluates processes of test laboratories or certifi-
947 cation bodies with respect to specific standard(s) or specification(s).

948 **Application Profile** - A selected subset of the product and / or standard which can be used to im-
949 plement a particular feature set or use case scenario.

950 **Attestation** - Issuance of a statement that fulfillment of specified requirements has been demon-
951 strated.

952 **Certificate** – Unique identifier of a particular product. It applies to both software and hardware
953 products. The certificate can be a physical or digital artifact (e.g., X.509 PKI schemes require digital
954 certificates).

955 **Certification** – Third-party attestation related to products, processes, systems or persons.

956 **Certification Bodies (CBs)** – The entity responsible for certifying that products have fulfilled the
957 requirements of a standard or specification.

958 **Compliant Portion Description (CPD)** – A CPD is a definitive manifest of all mandatory and op-
959 tional features implemented in a certified product. The CPD is generally used by product designers
960 to judge:

- 961 • Conformance of an implementation,
- 962 • Completeness of a system composed of pre-certified sub-components by compar-
963 ing each of the CPDs of those sub-components.
- 964 • Interoperability of two products based on matching feature sets as described by
965 their respective CPDs.

966 For example, a designer can compare the CPD with the test requirements to determine the level of
967 conformance of a product to a specification. When designing a product composed of pre-certified
968 sub-components, the respective CPDs will serve as selection criteria to design the complete prod-
969 uct. The CPD also helps to judge the level of interoperability that can be expected from interac-
970 tions between two independent implementations. A client service and a server function can be re-
971 viewed for their expected level of interoperability solely based on their respective CPDs.

Interoperability Process Reference Manual (IPRM)

972 **Conformance Certification** – A third-party attestation that a product conforms to a standard or
973 specification.

974 **Conformance Testing** – Determines whether an implementation conforms to the standard as writ-
975 ten. This is done by evaluating the implementation with a test tool such as an emulator, test har-
976 ness, golden unit, etc.

977 **Feature set** – A feature set is a particular characteristic of a product based on a particular use
978 case scenario. For example: signaling price is a feature set.

979 **First Party Testing** – is when an implementer self-tests their own product. This is usually permitted
980 after a technology has matured to where sufficient tools and specifications enabling first party test-
981 ing are available to all vendors.

982 **Golden Implementation/Units** – Test tools that can be configured in a laboratory to provide a
983 constant baseline or reference such that there is assurance that changes to the products making
984 up a system under test or configuration variants are consistently tested in the same manner

985 **Inheritance** – Those actions required to evaluate the compatibility of a proposed inherited design
986 including products, subsystem functions and design requirements.

987 **Interoperability** – Ability of a product or system to work with or integrate with another product or
988 system based on defined business requirements.

989 **Interoperability Testing** – Connects two or more implementations together and determines
990 whether they can successfully communicate. Significantly different from conformance testing, it is
991 often possible for two systems that conform to the standard to be unable to communicate. If they
992 can communicate, it is possible that they cannot perform any useful functions. These situations
993 arise because the implementations have conflicting interpretations of the specification, or because
994 they have chosen conflicting options within the standard. A particular form of interoperability test-
995 ing is application testing, in which there is a specification for the particular use of standard that can
996 be tested.

997 **Implementation Under Test (IUT)** – The implementation subject to testing. Covers System Under
998 Test (SUT) and Device Under Test (DUT)

Interoperability Process Reference Manual (IPRM)

- 999 **Multi-vendor and Multi-product Testing Event** – An interoperability test of products with other
1000 peer products. The outcome of the testing is used to improve both products and the specification.
- 1001 **Performance / Protocol / Proforma Implementation Conformance Statement (PICS)** – Defines
1002 all mandatory and optional feature sets of a specification that can be used to implement a product.
- 1003 **Platform level communications protocol** - In the IPRM, platform level communications protocols
1004 are integrated products based on standards only associated with layers 1 and 2 of the OSI layer.
1005 (e.g., Wi-Fi platform)
- 1006 **Second Party Testing** – Testing activities performed by buyers and users.
- 1007 **Security Testing** – Analyzes whether the implementation correctly makes use of any security fea-
1008 tures from the standard or other security features available in the product. This is the most difficult
1009 type of testing program since it must evaluate whether the system has vulnerabilities, which are not
1010 always obvious.
- 1011 **Standards Setting Organizations (SSOs)** - An association whose primary activities are develop-
1012 ing, coordinating, promulgating, revising, amending, re-issuing, interpreting, or otherwise maintain-
1013 ing standards. A Standards Developing Organization is one form of a Standards Setting Organiza-
1014 tion. Example SSOs including International Organization for Standardization (ISO), International
1015 Electro technical Commission (IEC), Institute of Electrical and Electronics Engineers (IEEE), Amer-
1016 ican National Standards Institute (ANSI), etc. An SSO can also be an industry trade association
1017 that develops industry standards such as the ZigBee Alliance.
- 1018 **Static Conformance Review** – A review of designed feature sets versus the specified PICS to
1019 determine the extent to which the features are supported by the IUT. This is the first step when a
1020 product enters a testing program. Generally the test lab requests that the implementer declare all
1021 supported feature sets in a product. This information is used to create the test plan for that product.
- 1022 **Test Cases** – A set of tests to verify a particular feature set. There are many ways to test a feature
1023 set, with each of those representing a test case. Generally, a program defines all possible test cas-
1024 es in the test specification document.
- 1025 **Test Case Reference List** – A current master list of all tests that are to be included into a product
1026 test plan. This list also indicates the time variable applicability of each test by reflecting those tests

Interoperability Process Reference Manual (IPRM)

1027 which are no longer valid, and those that are not currently valid but are scheduled to become active
1028 in the near future. This helps a product implementer in preparing fully conforming and interopera-
1029 ble products for an upcoming launch.

1030 **Test Harness** - Collection of software, test data, and hardware configured to test a product by op-
1031 erating it under varying conditions and monitoring its behavior and output.

1032 **Test Interface** - The programmatic application interface to enable communication between a test
1033 harness and system or device under test.

1034 **Test Plan** – A Test Plan is a list of applicable tests for a specific product and is derived from the
1035 Test Case Reference List.

1036 **Test Procedure** – A stepwise test method of a particular test case. An example of a test procedure
1037 can be the steps needed for an Energy Services Interface (ESI) to send price signals, which may
1038 include configuring the time information, updating price tables, etc.

1039 **Test Profile or Profile** - A select subset of a product and / or standard to implement a particular
1040 test of a feature or a use-case test. Test Profiles evaluate a subset of a TSS and are used to target
1041 specific areas of product interoperability.

1042 **Test Resource** - Any information, equipment, material, and support required to implement testing.

1043 **Testing** – According to EN 45020, testing is defined as “the technical operation that consists of the
1044 determination of one or more characteristics of a given product, process or service according to a
1045 specified procedure”.

1046 **Testing Laboratories (TLs)** – Test service providers for a standard or specification.

1047 **Test Suite Specification (TSS) or Test Spec-** Consists of a suite of tests, categorized into logical
1048 functional areas, such as use cases or well-defined features. Each test suite consists of many re-
1049 lated test cases corresponding to a particular feature set or use case. Test cases would include
1050 both valid and invalid behavior tests. Each test case is further described step-by-step with test pro-
1051 cedures and well defined pass / fail / indeterminate criteria, along with references.

Interoperability Process Reference Manual (IPRM)

- 1052 **Test Suite-** A collection of related test cases. A test suite can be put together to test a feature set.
1053 A pricing test case would be in a “price test suite” but a messaging test case would be in a “mes-
1054 saging test suite”.
- 1055 **Third Party Testing** – Testing activities performed by organizations independent of first or second
1056 parties.
- 1057 **Use Case** - A description of a system’s behavior as it responds to a request that originates from
1058 outside of that system
- 1059
